The Iris Flower Dataset

- Introduced by Ronald Fisher in his 1936 paper: **The use of multiple** measurements in taxonomic problems.
- Extensively used in the machine learning community for testing classification methods. https://en.wikipedia.org/wiki/Iris_flower_data_set

The Iris Flower Dataset

THE USE OF MULTIPLE MEASUREMENTS IN

By R. A. FISHER, Sch. ERS.

I. Descriminant punctions

Wars two or more populations have been measured in neveral characters, $s_1, \dots s_{r_s}$ special interest states the cortain linear function of the measurements by which the populations are best distributed as A to be subtor's suggestion one has already been made of this fact in rectangent φ to by A has already been made of this fact in rectangent φ to by A has already been made of this fact in rectangent φ to by A has already been such as already been such as already been such as a substant A has already A has a residue of the processes analysis of all lake A information of the processes analysed A has a residue of A has a region of the processes analysed A has a region of A has a region of the processes analysed A has a region of A has a region of A has a region o

II ADDRESS TO A PROCESS TO A

Table I shows measurements of the flowers of fifty plants each of the two species Iris eston and I. sersicoler, found growing together in the same colony and measured by De R. Andresse, to whom I am indebted for the use of the data. Four flower measurements are given. We shall first consider the question: What linear function of the four

measurements $X = \lambda_1 x_1 + \lambda_2 x_2 + \lambda_3 x_3 + \lambda_4 x_4$ will maximize the ratio of the difference between the specific means to the standard

deviations within species? The observed means and their differences are shown in Table II. We may represent the differences by d_p , where p-1, \hat{z} , 3 or 4 for the four measurements. The sums of squares and products of deviations from the specific means are shown in Table III. See five whether $d_p = d_p = d_p$

This sums of squares and produce to utwards out on these section access are shown in Table III. Since fifty plants of each species were used these sums contain 30 degrees of freedom. We may represent these sums of squares or products by S_{pq} , where p and q take independently the values 1, 2, 3 and 4.

Then for any linear function, X, of the measurements, as defined above, the difference

 $D = \lambda_1 d_1 + \lambda_2 d_2 + \lambda_3 d_3 + \lambda_4 d_4 + \lambda_4 d_4$

while the variance of X within species is proportional to

 $S = \sum_{p=1}^{4} \sum_{q=1}^{4} \lambda_{p} \lambda_{q} S_{pq}$

The particular linear function which best discriminates the two species will be one for

The Iris Flower Dataset - Plotting

Performing ANOVA Using Statistical Software

- Software choices
- R
- Python
- SAS
- Stata
- SPSS
- Minitab

Fisher's Least Significant Difference (LSD)

When doing *post hoc* pairwise *t*-tests, use the following test statistic (equal variance) for all comparisons:

$$m{t} = rac{ar{x}_1 - ar{x}_2}{\sqrt{ ext{MSW}\left(rac{1}{n_1} + rac{1}{n_2}
ight)}}, ext{where }
u = n - k$$

Note the difference between s_p^2 and MSW

One-way/factor ANOVA

- One-way/factor ANOVA: samples can be distinguished by one facotr:
- Brands of tyres
- Species
- etc.

- Two-way/factor ANOVA: samples can be distinguished by two facotrs:
- Brands of tyres + colours
- Species + location
- etc.
